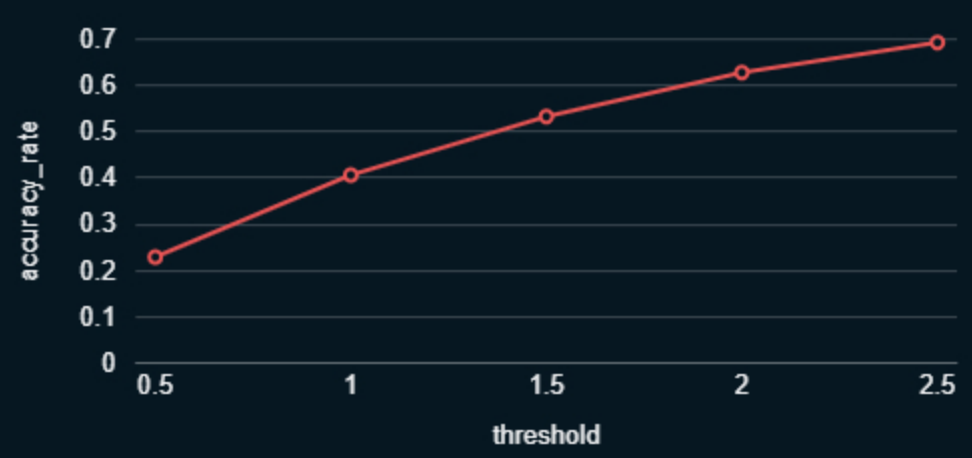
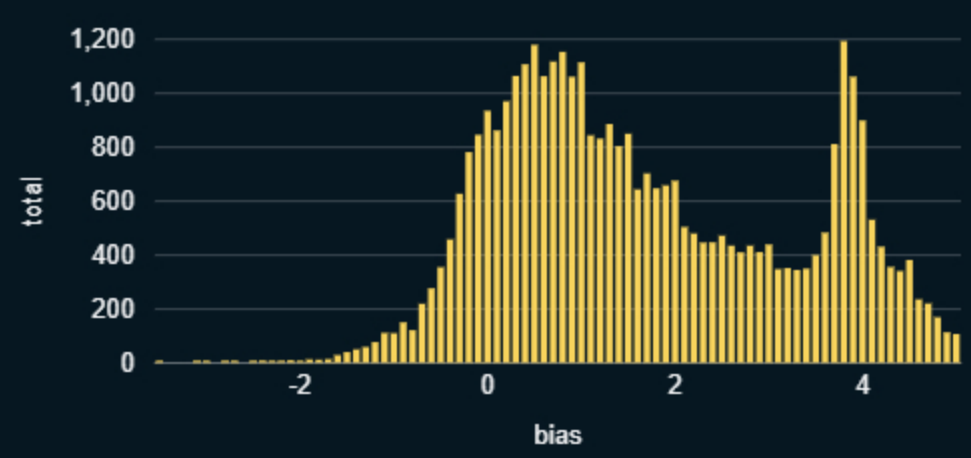
Statistics Overview

Cumulative Accuracy Curve

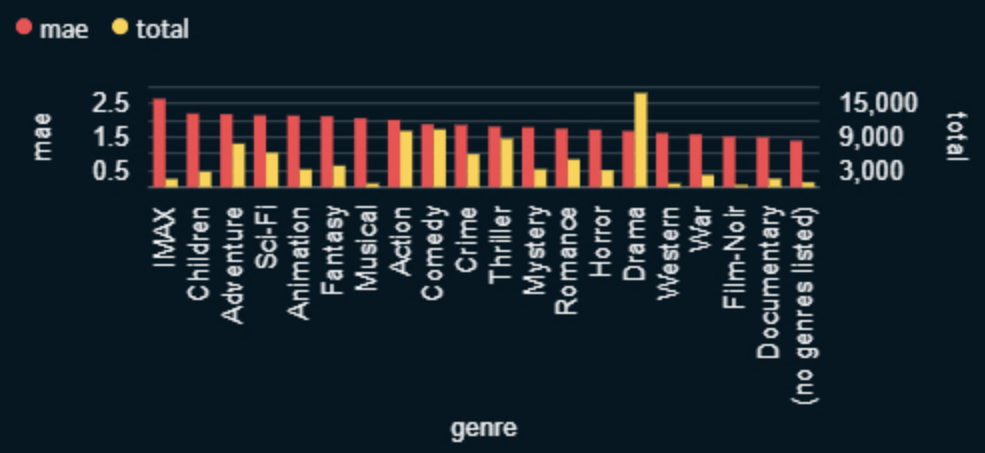


Prediction Bias Distribution



This chart shows the proportion of predictions that fall within increasing error thresholds. It provides a cumulative view of model accuracy across different tolerance levels.A steeper curve indicates better performance, as a higher percentage of predictions fall within lower error margins. This helps evaluate how the model performs under varying levels of acceptable error.

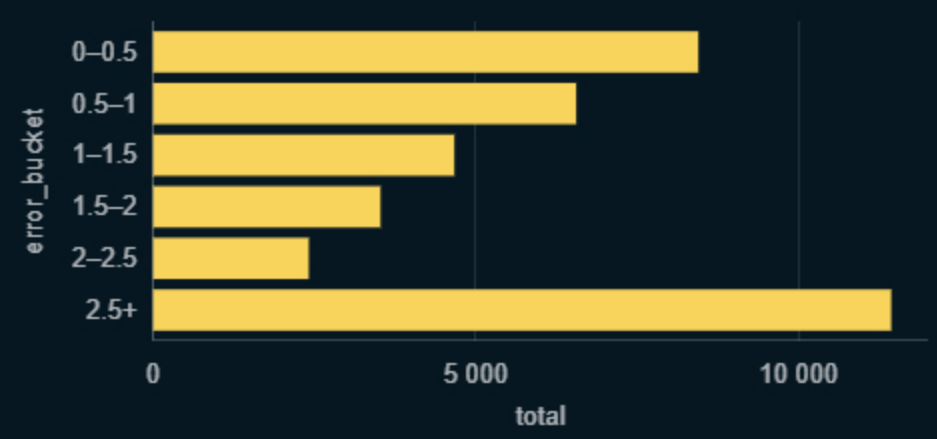
Prediction Error by Genre



This chart shows the average prediction error (MAE) by movie genre, highlighting how well the recommendation system performs across different content categories.Higher MAE values indicate genres where the model struggles to accurately predict user preferences, while lower values suggest better alignment between predicted and expected ratings.This analysis helps identify content segments where the recommendation model may require improvement or recalibration.

This chart shows the distribution of prediction bias, defined as the difference between system-predicted ratings and user-expected ratings.Values above zero indicate that the system tends to overestimate user preferences, while values below zero indicate underestimation.A well-calibrated model should have a distribution centered around zero, with minimal spread. A shift to the right suggests systematic overestimation, while a shift to the left indicates consistent underprediction.

Prediction Error Distribution



This chart shows the distribution of prediction errors between system-generated ratings and user-expected ratings. Each bar represents the number of predictions within a specific error range.A higher concentration of values in lower error ranges (e.g., 0–0.5) indicates better model performance, while a significant number of observations in higher error ranges suggests poor prediction accuracy and potential model miscalibration.
